Find the area under the curve $y = \sin(x)$
for $0 \leq x \leq \pi$
using the Trapezoid Rule

Exact answer: $\int_0^{\pi} (\sin x) dx = -\cos x \Big|_0^{\pi} = 2.0$

Don't do it this way !

3

```
const double A = 0.;
const double B = M_PI;
double dx = ( B - A ) / (float) ( numSubdivisions - 1 );
double sum = ( Function( A ) + Function( B ) ) / 2.;

omp_set_num_threads( numThreads );
#pragma omp parallel for default(none), shared(dx,sum)
for( int i = 1; i < numSubdivisions - 1; i++ )
{
    double x = A + dx * (float) i;
    double f = Function( x );
    sum += f;
}
sum *= dx;
```

- There is no guarantee when each thread will execute this line
- There is not even a guarantee that each thread will finish this line before some other thread interrupts it.

Assembly code:

```
Load sum
Add f
Store sum
```

What if the scheduler decides to switch threads right here?

The answer should be 2.0 *exactly*, but in 30 trials, it's not even close.⁴
And, the answers aren't even consistent. How do we fix this?

0.672593	0.548837
0.411158	0.363092
0.408718	0.544778
0.523448	0.356299

The answer should be 2.0 *exactly*, but in 30 trials, it's not even close.⁵
And, the answers aren't even consistent. How do we fix this?

There are Three Ways to Make the Summing Work Correctly:

#1: Atomic

6

1

```
#pragma omp parallel for shared(dx)
for( int i = 0; i < numSubdivisions; i++ )
{
    double x = A + dx * (float) i;
    double f = Function( x );
    #pragma omp atomic
    sum += f;
}
```

- More lightweight than *critical* (#2)
- Uses a hardware instruction CMPXCHG (compare-and-exchange)
- Can only handle these operations:

x++, ++x, x--, --x

x op= expr , x = x op expr , x = expr op x

where op is one of: +, -, *, /, &, |, ^, <<, >>

There are Three Ways to Make the Summing Work Correctly: #2: Critical

7

2

```
#pragma omp parallel for shared(dx)
for( int i = 0; i < numSubdivisions; i++ )
{
    double x = A + dx * (float) i;
    double f = Function( x );
    #pragma omp critical
    sum += f;
}
```

- More heavyweight than *atomic* (#1)
- Allows only one thread at a time to enter this block of code (similar to a mutex)
- Can have any operations you want in this block of code

There are Three Ways to Make the Summing Work Correctly:

#3: Reduction

3

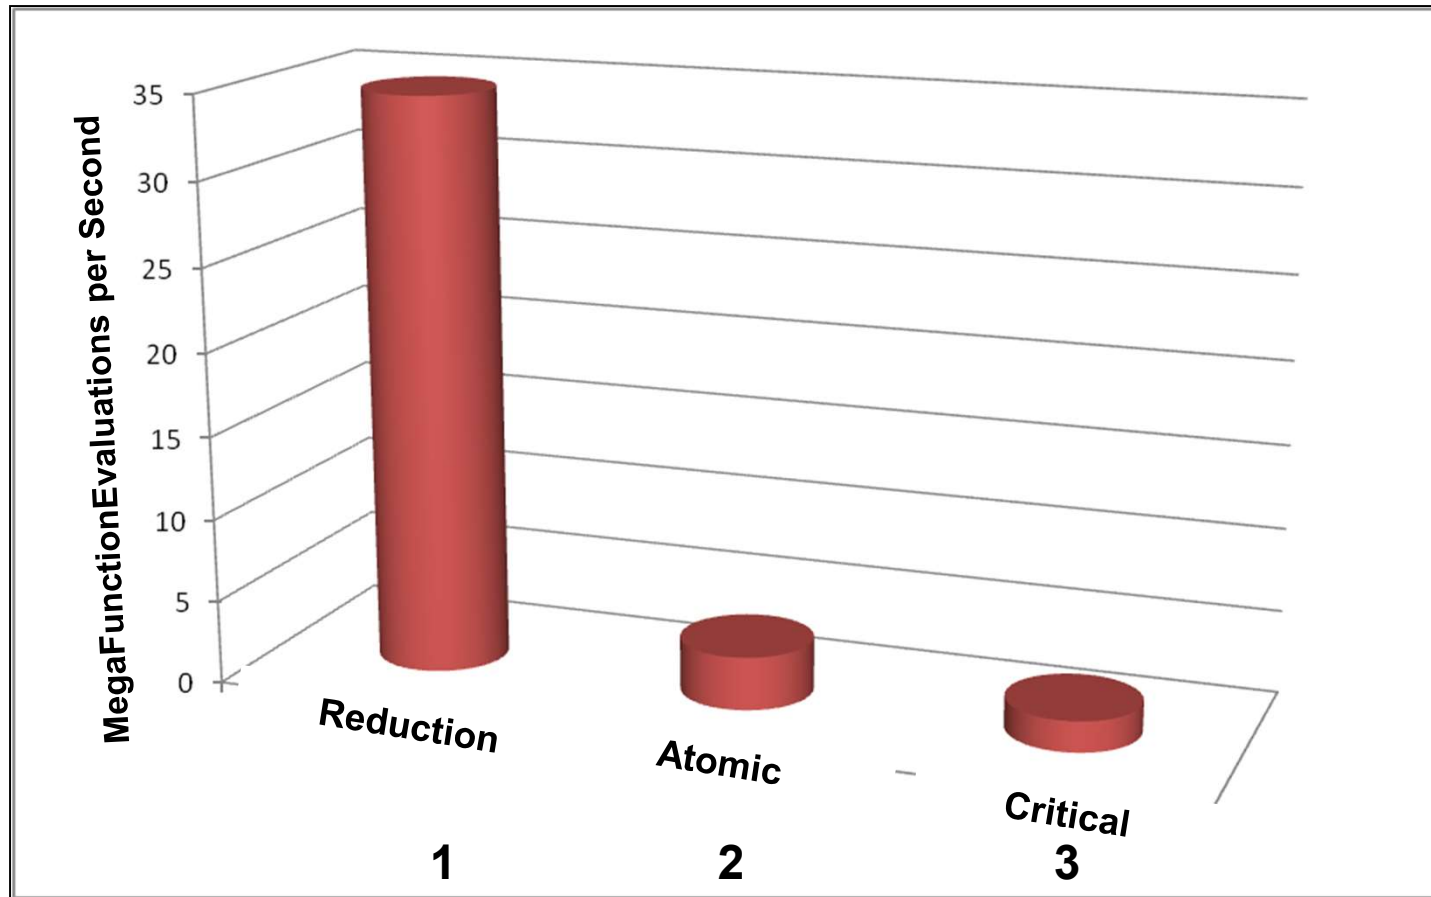

```
#pragma omp parallel for shared(dx), reduction(+:sum)
for( int i = 0; i < numSubdivisions; i++ )
{
    double x = A + dx * (float) i;
    double f = Function( x );
    sum += f;
}
```

- OpenMP creates code to make this as fast as possible
- Reduction operators can be: + , - , * , & , | , ^ , && , || , max , min

Speed of Reduction vs. Atomic vs. Critical

(up = faster)

— Performance —

So, do it this way !

10

```
const double A = 0.;
const double B = M_PI;

double dx = ( B - A ) / (float) ( numSubdivisions - 1 );

omp_set_num_threads( numThreads );

double sum = ( Function( A ) + Function( B ) ) / 2.;

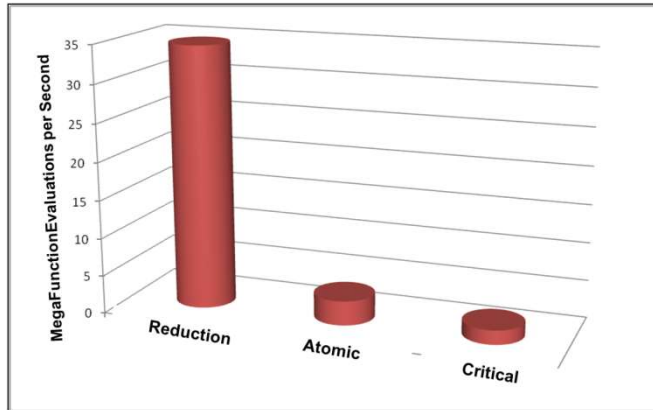

#pragma omp parallel for default(none),shared(dx),reduction(+:sum)
for( int i = 1; i < numSubdivisions - 1; i++ )
{
    double x = A + dx * (float) i;
    double f = Function( x );
    sum += f;
}

sum *= dx;
```

Two Reasons Why Reduction is so Much Better in this Case

11

```
#pragma omp parallel for shared(dx),reduction(+:sum)
for( int i = 0; i < numSubdivisions; i++ )
{
    double x = A + dx * (float) i;
    double f = Function( x );
    sum += f;
}
```

1. Reduction secretly creates a temporary private variable for each thread's running **sum**. Each thread adding into its own running **sum** doesn't interfere with any other thread adding into *its* own running **sum**, and so threads don't need to slow down to get out of the way of each other.
2. Reduction automatically creates a binary tree structure, like this, to add the N running sums in $\log_2 N$ time instead N time.

$O(N)$ vs. $O(\log_2 N)$

- Reduction automatically creates a binary tree structure, like this, to add the N running sums in $\log_2 N$ time instead N time.

Serial addition:

Adding 8 numbers requires 7 steps

Adding 1,048,576 (1M) numbers requires 1,048,575 steps

Parallel addition:

Adding 8 numbers requires 3 steps

Adding 1,048,576 (1M) numbers requires 20 steps

If You Understand NCAA Basketball Brackets, You Understand Power-of-Two Reduction 13

Why Not Do Reduction by Creating Your Own *sums* Array, one for each Thread, Like This?

```
float *sums = new float [ omp_get_num_threads( ) ];
for( int i = 0; i < omp_get_num_threads( ); i++ )
    sums[ i ] = 0.;

#pragma omp parallel for private(myPartialSum),shared(sums)
for( int i = 0; i < N; i++ )
{
    myPartialSum = ...

    sums[ omp_get_thread_num( ) ] += myPartialSum;
}

float sum = 0.;
for( int i = 0; i < omp_get_num_threads( ); i++ )
    sum += sums[ i ];

delete [ ] sums;
```

- This seems perfectly reasonable, it works, and it gets rid of the problem of multiple threads trying to write into the same reduction variable.
- The reason we don't do this is that this method provokes a problem called **False Sharing**. We will get to that when we discuss caching.
